Ammi:

Decoders

A decoder is a digital circuit that detects the presence of a specified combination of bits (code) on its inputs and indicates the presence of that code by a specified output level.

a decoder has n input lines to handle n bits and from one to 2^n output lines

Basic Binary Decoder
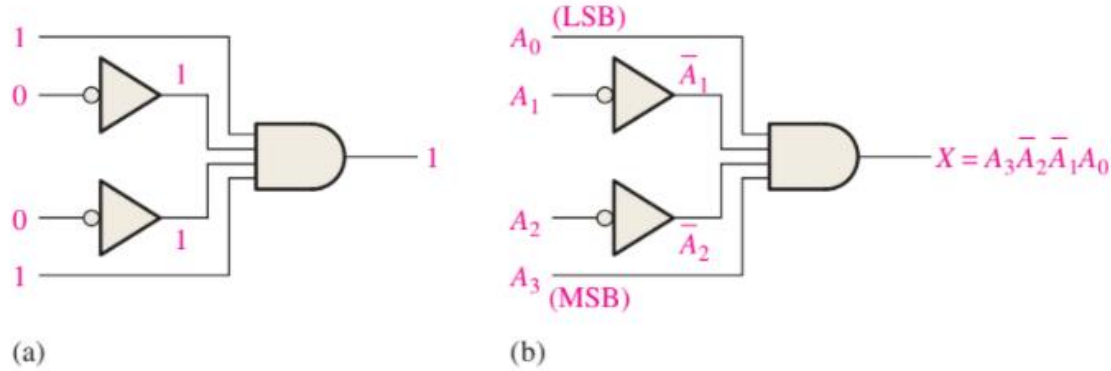

FIGURE 6-26 Decoding logic for the binary code 1001 with an active-HIGH output.

Determine the logic required to decode the binary number 1011 by producing a HIGH level on the output.

4 Bit Decoder

To decode all possible combinations of four bits, sixteen decoding gates are required (2^4 = 16).

4-line-to-16-line decoder because there are four inputs and sixteen outputs

1-of-16 decoder because for any given code on the inputs, one of the sixteen outputs is activated.

Decimal to BCD Priority Encoders

The priority function means that the encoder will produce a BCD output corresponding to the highest-order decimal digit input that is active.

For instance, if the 6 and the 3 inputs are both active, the BCD output is 0110 (which represents decimal 6).

Code Converter

BCD-to-Binary Conversion:

1. The value, or weight, of each bit in the BCD number is represented by a binary number.

2. All of the binary representations of the weights of bits that are 1s in the BCD number are added.

3. The result of this addition is the binary equivalent of the BCD number.

The binary numbers representing the weights of the BCD bits are summed to produce the total binary number.

MultiPlexers (MUX)

Allows digital information from several sources to be routed onto a single line for transmission over that line to a common destination.

It has several data-input lines and a single output line.

It also has data-select inputs, which permit digital data on any one of the inputs to be switched to the output line.

Also known as data selectors.

Applications: Router, Telephone Network, Computer memory

Multiplexers (MUX)

1	1	D_3

The data output is equal to D_0 only if $S_1 = 0$ and $S_0 = 0$: $Y = D_0\overline{S}_1\overline{S}_0$.

The data output is equal to D_1 only if $S_1 = 0$ and $S_0 = 1$: $Y = D_1\overline{S}_1 S_0$.

The data output is equal to D_2 only if $S_1 = 1$ and $S_0 = 0$: $Y = D_2 S_1\overline{S}_0$.

The data output is equal to D_3 only if $S_1 = 1$ and $S_0 = 1$: $Y = D_3 S_1 S_0$.
